Examples of Relational/Algebraic Structures: Posets, Lattices, Heyting Algebras, Boolean Algebras, and more

(OPTIONAL)

Assaf Kfoury

Oct 1, 2020

Algebraic Structures: definitions and examples

- ▶ An **algebraic structure** \mathcal{A} , or just an **algebra** \mathcal{A} , is a set A , called the **carrier set** or **underlying set** of \mathcal{A} , with one or more operations on the carrier A . (Search the Web, [here](#) and [here](#), for more details.)
- ▶ Examples of **algebraic structures**:

- ▶ $(\mathbb{Z}, =, +, \cdot)$
the set of integers with **binary** operations addition “+” and multiplication “·”,
- ▶ $(\mathbb{N}, =, \text{succ}, \text{pred}, 0, 1)$
the set of natural numbers with **unary** operations, “succ” and “pred”,
and **nullary** operations, “0” and “1”,
- ▶ $(T, =, \text{node}, \text{Lt}, \text{Rt})$ where T is the least set such that:

$$T \supseteq \{a, b, c\} \cup \{ \langle t_1 \ t_2 \rangle \mid t_1, t_2 \in T \}$$

with one **binary** operation “node” and two **unary** operations “Lt” and “Rt”,
defined by:

Algebraic Structures: definitions and examples

$$\text{node} : T \times T \rightarrow T \quad \text{where } \text{node}(t_1, t_2) \stackrel{\text{def}}{=} \langle t_1 \ t_2 \rangle$$

$$\text{Lt} : T \rightarrow T \quad \text{where } \text{Lt}(t) \stackrel{\text{def}}{=} \begin{cases} t_1 & \text{if } t = \langle t_1 \ t_2 \rangle, \\ \text{undefined} & \text{otherwise.} \end{cases}$$

$$\text{Rt} : T \rightarrow T \quad \text{where } \text{Rt}(t) \stackrel{\text{def}}{=} \begin{cases} t_2 & \text{if } t = \langle t_1 \ t_2 \rangle, \\ \text{undefined} & \text{otherwise.} \end{cases}$$

- ▶ Sometimes an **algebraic structure** includes two (or more) carriers, together with operations between them, in which case we say the algebraic structure is **two-sorted** (or **multi-sorted**).
- ▶ Examples of **two-sorted algebraic structures**:
 - ▶ $(\mathbb{Z}, \mathbb{B}, =, \leq, +, \cdot)$ where $\mathbb{B} \stackrel{\text{def}}{=} \{\mathbf{F}, \mathbf{T}\}$ and $\leq : \mathbb{Z} \times \mathbb{Z} \rightarrow \mathbb{B}$.
 - ▶ $(T, \mathbb{N}, =, \text{node}, \text{Lt}, \text{Rt}, |, \text{height})$ where T is defined on previous slide, with $| : T \rightarrow \mathbb{N}$ and $\text{height} : T \rightarrow \mathbb{N}$.

Algebraic Structures: definitions and examples

- ▶ For a 2-sorted structure such as $\mathcal{M} \stackrel{\text{def}}{=} (T, \mathbb{N}, =, \text{node}, \text{Lt}, \text{Rt}, |, |, \text{height})$, we need to introduce two unary relation symbols, say R_1 and R_2 , whose interpretations are the domains T and \mathbb{N} :

$$R_1^{\mathcal{M}} \stackrel{\text{def}}{=} T \quad \text{and} \quad R_2^{\mathcal{M}} \stackrel{\text{def}}{=} \mathbb{N}$$

- ▶ \mathcal{M} satisfies the first-order sentence:

$$(\forall x. R_1(x) \vee R_2(x)) \wedge \neg(\exists x. R_1(x) \wedge R_2(x))$$

- ▶ To assert that an element of the first domain T satisfies a wff $\varphi(x)$ with one free variable x , we write:

$$\exists x. R_1(x) \wedge \varphi(x)$$

(The book [LCS], Chapter 2, does not deal with multi-sorted structures.)

Algebraic Structures: definitions and examples

- ▶ Sometimes in a **two-sorted algebraic structure**, such as $(\mathbb{Z}, \mathbb{B}, =, \leq, +, \cdot)$ with the Boolean carrier \mathbb{B} one of the two sorts, we can omit \mathbb{B} and simply write $(\mathbb{Z}, =, \leq, +, \cdot)$.
- ▶ This assumes that it is clear to the reader that “ \leq ” is a function from $\mathbb{Z} \times \mathbb{Z}$ to \mathbb{B} , *i.e.*, “ \leq ” is a binary **relation** (rather than a binary **function** or **operation**). As a binary relation, we can write:
 $\leq \subseteq \mathbb{Z} \times \mathbb{Z}$.
- ▶ Strictly speaking, a structure such as $(\mathbb{Z}, =, \leq, +, \cdot)$, which now includes **operations** as well as **relations**, is called a **relational structure** rather than just an algebraic structure.
- ▶ But the transition from **algebraic structures** to more general **relational structures** is not demarcated sharply.
- ▶ In particular, if a structure \mathcal{A} includes one or two relations with standard meanings (such as “ \leq ”), we can continue to call \mathcal{A} an **algebraic structure**.

Posets: definitions and examples

- A **partially ordered set**, or **poset** for short, is a set P with a **partial ordering** \leq on P , i.e., for all $a, b, c \in P$, the ordering \leq satisfies:

$$a \leq a \quad \text{“} \leq \text{ is reflexive”}$$

$$(a \leq b \text{ and } b \leq a) \text{ imply } a = b \quad \text{“} \leq \text{ is anti-symmetric”}$$

$$(a \leq b \text{ and } b \leq c) \text{ imply } a \leq c \quad \text{“} \leq \text{ is transitive”}$$

The ordering \leq is **total** if it also satisfies for all $a, b \in P$:

$$(a \leq b) \text{ or } (b \leq a)$$

- Examples of **posets**:

- (1) $(2^A, \leq)$ where A is a non-empty set and \leq is \subseteq ,
- (2) $(\mathbb{N} - \{0\}, \leq)$ where $m \leq n$ iff “ m divides n ”,
- (3) (\mathbb{N}, \leq) where \leq is the usual ordering \leq .

In (1) and (2), \leq is **not total**; in (3), \leq is **total**.

Lattices: definitions and examples

- ▶ An **lattice** \mathcal{L} is an algebraic structure (L, \leq, \vee, \wedge) where \vee and \wedge are **binary operations**, and \leq is a **binary relation**, such that:
 - ▶ (L, \leq) is a poset,
 - ▶ for all $a, b \in L$, the **least upper bound** of a and b in the ordering \leq
 - ▶ exists,
 - ▶ is unique,
 - ▶ and is the result of the operation " $a \vee b$ ",
 - ▶ for all $a, b \in L$, the **greatest lower bound** of a and b in \leq
 - ▶ exists,
 - ▶ is unique,
 - ▶ and is the result of the operation " $a \wedge b$ ".
- ▶ Examples of **lattices**:
 - ▶ $(2^A, \leq, \vee, \wedge)$ where \leq is \subseteq , \vee is \cup , \wedge is \cap
 - ▶ $(\mathbb{N} - \{0\}, \leq, \vee, \wedge)$
where $m \leq n$ iff " m divides n ", \vee is "lcm", \wedge is "gcd"

Distributive Lattices: definitions and examples

- ▶ A lattice $\mathcal{L} = (L, \leq, \vee, \wedge)$ is a **distributive lattice** if for all $a, b, c \in L$, the following **equations** – also called **axioms** or **equational axioms** – are satisfied:

$$a \wedge (b \vee c) = (a \wedge b) \vee (a \wedge c) \quad \text{“}\wedge\text{” distributes over “}\vee\text{”}$$

$$a \vee (b \wedge c) = (a \vee b) \wedge (a \vee c) \quad \text{“}\vee\text{” distributes over “}\wedge\text{”}$$

- ▶ Example of a **distributive lattice**:

$$(2^A, \subseteq, \cup, \cap)$$

- ▶ Is the following an example of a **distributive lattice**?

$$(\mathbb{N} - \{0\}, \text{“} _ \text{ divides } _ \text{”, lcm, gcd})$$

- ▶ For more details on **posets** and **lattices**, go to the Web: **here** (Hasse diagrams), **here** (distributive lattices), and **here**.

Bounded Lattices: definitions and examples

- ▶ A **bounded lattice** is an algebraic structure of the form

$$\mathcal{L} = (L, \leq, \vee, \wedge, \underset{\uparrow}{\perp}, \underset{\uparrow}{\top})$$

where \perp and \top are **nullary** (or **0-ary**) **operations** on L (or, equivalently, **elements** in L) such that:

1. $\mathcal{L} = (L, \leq, \vee, \wedge)$ is a lattice,
2. $\perp \leq a$ or, equivalently, $\perp \wedge a = \perp$ for every $a \in L$,
3. $a \leq \top$ or, equivalently, $a \vee \top = \top$ for every $a \in L$.

The elements \perp and \top are uniquely defined. \perp is the **minimum** element, and \top is the **maximum** element, of the bounded lattice.

- ▶ Example of a **bounded lattice**: $(2^A, \subseteq, \cup, \cap, \underset{\uparrow}{\emptyset}, \underset{\uparrow}{A})$
- ▶ Example a **lattice** with a minimum, but **no** maximum:

$$(\mathbb{N} - \{0\}, \text{"-- divides --"}, \text{lcm}, \text{gcd}, \underset{\uparrow}{1})$$

Bounded Lattices: definitions and examples

- Let $\mathcal{L} = (L, \preceq, \vee, \wedge, \perp, \top)$ be a **bounded lattice**. An element $a \in L$ has a **complement** $b \in L$ iff:

$$a \wedge b = \perp \quad \text{and} \quad a \vee b = \top$$

FACT: In a **bounded distributive lattice**, **complements** are uniquely defined, *i.e.*, an element $a \in L$ cannot have more than one complement $b \in L$.

Proof. Exercise.

Complemented Lattices: definitions and examples

- ▶ A **complemented lattice** is a **bounded distributive lattice** $\mathcal{L} = (L, \leq, \vee, \wedge, \perp, \top)$ where every element has a complement.
- ▶ Example of a **complemented lattice**: $(2^A, \subseteq, \cup, \cap, \emptyset, A)$
- ▶ Again, for more details various kinds of **lattices**, go to the Web: [here](#) (Hasse diagrams), [here](#) (distributive lattices), [here](#) (lattices).

Boolean Algebras: definitions and examples

- ▶ A **complemented lattice** $\mathcal{L} \stackrel{\text{def}}{=} (L, \leq, \vee, \wedge, \perp, \top)$ is almost a **Boolean algebra**, but not quite!

What is missing is an **additional operation** on L to map an element $a \in L$ to its **complement**.

- ▶ A first definition of a **Boolean algebra**:

$$\mathcal{L} \stackrel{\text{def}}{=} (L, \leq, \vee, \wedge, \perp, \top, \underbrace{\neg}_{\uparrow})$$

where:

1. $\mathcal{L} \stackrel{\text{def}}{=} (L, \leq, \vee, \wedge, \perp, \top)$ is a **complemented lattice**,
2. The new operation “ \neg ” is **unary** and maps every $a \in L$ to its complement, *i.e.*:

$$a \wedge (\neg a) = \perp \quad \text{and} \quad a \vee (\neg a) = \top$$

Boolean Algebras: definitions and examples

- ▶ A second definition of a **Boolean algebra**
(easier to compare with Heyting algebras later) :

$$\mathcal{L} \stackrel{\text{def}}{=} (L, \leq, \vee, \wedge, \perp, \top, \underset{\uparrow}{\rightarrow})$$

where:

1. $\mathcal{L} \stackrel{\text{def}}{=} (L, \leq, \vee, \wedge, \perp, \top)$ is a **complemented lattice**,
 2. The new operation “ \rightarrow ” is **binary** such that $(a \rightarrow \perp)$ is the complement of a , for every every $a \in L$.
- ▶ **FACT:** The two preceding definitions of **Boolean algebras** are equivalent because we can define “ \rightarrow ” in terms of $\{\vee, \neg\}$:

$$a \rightarrow b \stackrel{\text{def}}{=} (\neg a) \vee b$$

as well as define “ \neg ” in terms of $\{\rightarrow, \perp\}$:

$$\neg a \stackrel{\text{def}}{=} a \rightarrow \perp$$

Boolean Algebras: definitions and examples

- ▶ Examples of **Boolean algebras**:

- ▶ For an arbitrary non-empty set A :

$$(2^A, \subseteq, \cup, \cap, \emptyset, A, \neg)$$

where $\overline{X} \stackrel{\text{def}}{=} A - X$ for every $X \subseteq A$.

- ▶ The standard 2-element Boolean algebra:

$$(\{0, 1\}, \leq, \vee, \wedge, 0, 1, \neg) \quad \text{or} \quad (\{0, 1\}, \leq, \vee, \wedge, 0, 1, \rightarrow)$$

where we write “0” for **F** and “1” for **T**.

Heyting Algebras: definitions and examples

- ▶ A **Heyting algebra** is an algebraic structure of the form

$$\mathcal{L} \stackrel{\text{def}}{=} (L, \leq, \vee, \wedge, \perp, \top, \overset{\uparrow}{\rightarrow})$$

where:

- ▶ $\mathcal{L} \stackrel{\text{def}}{=} (L, \leq, \vee, \wedge, \perp, \top)$ is a **bounded distributive lattice** – **not** necessarily a *complemented lattice*,
- ▶ The new operation “ \rightarrow ” is **binary** and satisfies the **equations**:
 1. $a \rightarrow a = \top$
 2. $a \wedge (a \rightarrow b) = a \wedge b$
 3. $a \rightarrow (b \wedge c) = (a \rightarrow b) \wedge (a \rightarrow c)$
 4. $b \leq a \rightarrow b$

FACT: The preceding equations uniquely define the operation “ \rightarrow ”.
Proof. Exercise.

- ▶ **FACT:** Every Boolean algebra is a Heyting algebra. *Proof.* Exercise.
